The proceedings of the workshop were jointly and simultaneously published in the Journal of Periodontology and Journal of Clinical Periodontology.

Abstract

While plaque-induced gingivitis is one of the most common human inflammatory diseases, several non–plaque-induced gingival diseases are less common but often of major significance for patients. The non–plaque-induced gingival lesions are often manifestations of systemic conditions, but they may also represent pathologic changes limited to gingival tissues. A classification is proposed, based on the etiology of the lesions and includes: Genetic/Developmental disorders; Specific infections; Inflammatory and immune conditions and lesions; Reactive processes; Neoplasms; Endocrine, Nutritional and metabolic diseases; Traumatic lesions; and Gingival pigmentation.

KEYWORDS
classification, diagnosis oral, epulis, gingiva, gingival diseases, immunological, inflammation, mouth mucosa, oral manifestations, oral medicine, periodontal disease, rare diseases

Human gingiva as well as other oral tissues may exhibit several non–plaque-induced pathologic lesions, which may in some instances be manifestations of a systemic condition or a medical disorder. They may also represent pathologic changes limited to gingival tissues. Although these lesions are not directly caused by plaque, their clinical course may be impacted by plaque accumulation and subsequent gingival inflammation. Dentists are the key healthcare providers in establishing diagnoses and formulating treatment plans for patients affected by such lesions. Specialists in periodontology should be familiar with and be able to diagnose, treat, or refer for treatment any such lesion.

A review of non–plaque-induced gingival lesions was presented at the 1999 International Workshop for a Classification of Periodontal Diseases and Conditions,1 and the present review aims to add available additional literature as well as diseases and conditions which were not included in the former review. Several of the diseases and their treatment have been reviewed recently.2–4 The purpose of the current review is not to repeat the details of such texts, but to present a contemporary classification of the most relevant non–plaque-induced gingival diseases and conditions (Table 1) and to discuss briefly the more common of these. The major difference between the present classification proposal and that of the 1999 workshop is creation of a more comprehensive nomenclature and inclusion of ICD-10 diagnostic codes. Because some of the conditions seldom manifest in the oral cavity and some even more seldom present gingival manifestations, detailed appraisal is included within Table 2.

DESCRIPTION OF SELECTED DISEASE ENTITIES:

1 | GENETIC/DEVELOPMENTAL ABNORMALITIES

1.1 | Hereditary gingival fibromatosis (HGF)

Clinically, gingival fibromatosis may present gingival overgrowth in various degrees. Compared to drug-related gingival overgrowth, hereditary gingival fibromatosis is a rare disease which may occur as an isolated disease or as part of a syndrome. It has a genetic basis in mutations of the Son of Sevenless gene5 (see Table 2).
### TABLE 1 (Continued)

6 Endocrine, nutritional, and metabolic diseases

6.1 Vitamin deficiencies
- Vitamin C deficiency (scurvy)

7 Traumatic lesions

7.1 Physical/mechanical insults
- Frictional keratitis
- Toothbrushing-induced gingival ulceration
- Factitious injury (self-harm)

7.2 Chemical (toxic) insults
- Etching
- Chlorhexidine
- Acetylsalicylic acid
- Cocaine
- Hydrogen peroxide
- Dentifrice detergents
- Paraformaldehyde or calcium hydroxide

7.3 Thermal insults
- Burns of mucosa

8 Gingival pigmentation
- Gingival pigmentation/melanoplakia
- smoker's melanosis
- Drug-induced pigmentation (antimalarials; minocycline)
- Amalgam tattoo

---

#### 2 SPECIFIC INFECTIONS

**2.1 Bacterial origin**

Necrotizing periodontal disease

Necrotizing periodontal diseases (*Treponema* spp., *Selenomonas* spp., *Fusobacterium* spp., *Prevotella intermedia*, and others)

*Neisseria gonorrhoeae* (gonorrhea)

*Treponema pallidum* (syphilis)

*Mycobacterium tuberculosis* (tuberculosis)

Streptococcal gingivitis (strains of streptococcus)

**2.2 Viral origin**

- Coxsackie virus (hand-foot-and-mouth disease)
- Herpes simplex 1/2 (primary or recurrent)
- Varicella-zoster virus (chicken pox or shingles affecting V nerve)
- Molluscum contagiosum virus
- Human papilloma virus (squamous cell papilloma, condyloma acuminatum, verruca vulgaris, and focal epithelial hyperplasia)

**2.3 Fungal**

- Candidosis
- Other mycoses (e.g., histoplasmosis, aspergillosis)

**3 Inflammatory and immune conditions and lesions**

3.1 Hypersensitivity reactions

- Contact allergy
- Plasma cell gingivitis
- Erythema multiforme

3.2 Autoimmune diseases of skin and mucous membranes

- Pemphigus vulgaris
- Pemphigoid
- Lichen planus
- Lupus erythematosus

3.3. Granulomatous inflammatory conditions (orofacial granulomatosis)

- Crohn's disease
- Sarcoidosis

**4 Reactive processes**

4.1 Epulides

- Fibrous epulis
- Calcifying fibroblastic granuloma
- Pyogenic granuloma (vascular epulis)
- Peripheral giant cell granuloma (or central)

**5 Neoplasms**

5.1 Premalignant

- Leukoplakia
- Erythroplakia

5.2 Malignant

- Squamous cell carcinoma
- Leukemia
- Lymphoma

2.2 Viral origin

The most important viruses to cause gingival manifestations are Coxsackie viruses and the herpes viruses including herpes simplex virus types 1 (HSV-1) and 2 (HSV-2) and varicella-zoster virus. Although these viruses most often infect individuals in childhood, primary infections may occur in adult life as well. They may give rise to oral mucosal disease followed by periods of latency and sometimes reactivation.

Coxsackie viruses

Coxsackie viruses may cause herpangina and hand-foot-and-mouth disease (synonym: vesicular stomatitis with exanthema). While herpangina does not involve gingiva, hand-foot-and-mouth disease is a common contagious vesicular viral disease affecting skin and oral mucosa including gingiva. The lesions are primarily seen in children and mainly caused by coxsackie viruses A6, A10, and A16 (see Table 2).

HSV-1 and HSV-2

HSV-1 usually causes oral manifestations, in contrast to HSV-2, which is primarily involved in anogenital infections and only occasionally in oral infections.

Herpetic gingivostomatitis

*Primary herpetic infection* typically occurs in infants and has an incubation period of 1 week. It may run an asymptomatic course in early childhood, but it may also give rise to gingivostomatitis with severe manifestations. A characteristic feature is the formation of few or many vesicles, which rupture, coalesce, and leave fibrin-coated ulcers often of irregular extension (Table 2).
Recurrent intraoral herpes simplex lesions typically occur in adults and have a much less dramatic course (Table 2). As a result, they may remain undiagnosed or mistaken for aphthous ulcerations, despite the fact that aphthous ulcers do not typically affect keratinized mucosa.

Varicella-zoster virus
The primary infection of varicella-zoster virus causes varicella (chicken pox), which occurs mainly in children (Table 2). Later reactivation of the virus in adults causes herpes zoster (shingles) with unilateral lesions following the distribution of an infected nerve. If the second or third branch of the trigeminal nerve is involved, skin lesions may be associated with intraoral lesions, including gingival lesions, and intraoral lesions may occur alone. Initial symptoms are pain and paresthesia, which may be present before lesions appear. The initial lesions are vesicles, which soon rupture and leave fibrin-coated small ulcers, often coalescing to irregular forms (Table 2).

Molluscum contagiosum virus
Molluscum contagiosum virus of the poxvirus family causes molluscum contagiosum, which is a contagious disease with infrequent oral manifestations (Table 2). It is seen in infants with immature immune systems and manifests as discrete umbilicated papules on the skin. In adults, the disease appears in the genital areas and is often sexually transmitted.

Human papilloma virus (HPV)
More than 100 types of HPV have been identified, and at least the following 25 types have been detected in oral lesions: 1, 2, 3, 4, 6, 7, 10, 11, 13, 16, 18, 31, 32, 33, 35, 40, 45, 52, 55, 57, 58, 59, 69, 72, 73. The benign oral lesions, associated with HPV infection, include squamous cell papilloma, condyloma acuminatum, verruca vulgaris, and focal epithelial hyperplasia, and they appear to be associated with different distinct HPV subtypes. Oral benign HPV lesions are mostly asymptomatic, and may persist or regress spontaneously (Table 2).

2.3 | Fungal origin
A number of fungi may give rise to oral infections, including candidiasis, histoplasmosis, aspergillosis, blastomycosis, coccidioidomycosis, paracoccidioidomycosis, cryptococcosis, geotricosis, mucormycosis. Several of these are uncommon, and oral manifestations may more likely occur with immune deterioration. Oral mycoses can cause acute, chronic, and mucocutaneous lesions. Candidosis is the most common mouth mycosis, while histoplasmosis and aspergillosis are less common (Table 2).

Candidosis
Several candida species may be isolated from the mouth of humans, including C. albicans, C. glabrata, C. krusei, C. tropicalis, C. parapsilosis, and C. guillermondii. The most common fungal infection of the oral mucosa is candidosis mainly caused by C. albicans. C. albicans is a normal commensal organism of the oral cavity but also an opportunistic pathogen. While candidal infection can be seen anywhere in the oral mucosa, lesions of the gingiva are seldom seen in otherwise healthy individuals. The most common clinical characteristic of gingival candidal infection is redness of the attached gingiva, often with a granular surface. Nodular gingival lesions are uncommon and are characterized by slightly elevated nodules of a white or reddish color. Diagnosis of candidal infection can be accomplished on the basis of culture, smear, and biopsy. “Linear gingival erythema” described in the 1999 International Workshop, sometimes associated with HIV infection, is now generally regarded as gingival candidosis and has therefore been removed from this classification.

3 | INFLAMMATORY AND IMMUNE CONDITIONS AND LESIONS
3.1 | Hypersensitivity reactions
Contact allergy
Oral mucosal manifestations of hypersensitivity (allergy) are very uncommon. As mentioned in the 1999 classification review, such reactions may be due to dental restorative materials, dentifrices, mouthwashes, and foods and are most often type IV hypersensitivity reactions (contact allergy).

Plasma cell gingivitis
Plasma cell gingivitis is an uncommon inflammatory condition usually affecting the anterior maxillary gingiva and of uncertain etiology. While some authors have associated plasma cell gingivitis with a hypersensitivity response to antigens in various substances, others have raised doubt whether plasma cell gingivitis is a distinct clinicopathologic entity.

Erythema multiforme (EM)
EM is an uncommon, self-limiting, acute immune-inflammatory disorder of the oral mucosa (Table 2). The etiology of EM is unclear in most patients, but it appears to be an immunologic hypersensitivity reaction mediated by T-lymphocytes. The disorder may present a diagnostic dilemma because infections (particularly, herpes simplex and mycoplasma pneumoniae) and some drugs seem to predispose toward the development of erythema multiforme, in what are believed to be immune complex disorders.
3.2 | Autoimmune diseases of skin and mucous membranes

Pemphigus vulgaris (PV)

PV is an autoimmune vesiculo-bullous disease of skin and mucous membranes. Involvement of the oral mucosa is common, and in about 54% of cases, the oral cavity has been reported to be the primary site of involvement. The disease is characterized by intraepithelial bullae in skin and mucous membranes due to auto-antibodies directed against desmosome-associated protein antigens (desmoglein-3). Oral mucosal lesions, including gingival lesions, may precede skin involvement. In the literature, gingival localization of PV usually manifests as desquamative gingivitis and/or as vesiculo-bullous lesions of the free and attached gingiva; early lesions only rarely appear as extensive erythema and erosions (Table 2).

Pemphigoid

Pemphigoid is a group of mucocutaneous disorders caused by autoantibodies toward antigens of the basement membrane, resulting in detachment of the epithelium from the connective tissue. If only mucous membranes are affected, the term mucous membrane pemphigoid (MMP) is often used. Scarring is an important ocular complication but not for oral mucosal lesions. Any area of the oral mucosa may be involved in MMP, but the main clinical manifestation is desquamative lesions of the gingiva presenting as intensely erythematous areas (Table 2). Usually the bullae rupture rapidly, leaving fibrin-coated ulcers. The separation of epithelium from connective tissue at the basement membrane area is the main diagnostic feature of MMP, and circulating serum antibodies are not always revealed by indirect immunofluorescence.

Lichen planus

Lichen planus is a common mucocutaneous disease with frequent manifestation on the gingiva. Oral involvement alone is common, and concomitant skin lesions in patients with oral lesions have been found in 5% to 44% of the cases. The major characteristic of this disease is an inflammatory reaction toward an unidentified antigen in the basal epithelial layer/basement membrane zone. The disease may be associated with severe discomfort. Because it has been shown to possess a premalignant potential, it is important to diagnose, treat, and follow patients through regular oral examinations. Six types of clinical manifestation have been described (Table 2). The lesions, usually bilateral, often involve the gingiva and present as desquamative gingivitis causing pain and discomfort during eating and toothbrushing. The clinical diagnosis is based on the presence of papular- or reticular-type lesions, eventually supported by histopathologic findings of hyperkeratosis, degenerative changes of basal cells, and subepithelial inflammation dominated by lymphocytes and macrophages. In a recent randomized controlled trial, a tailored plaque-control regime was shown to be beneficial in reducing symptoms of gingival lichen planus and improving overall quality of life.

Lupus erythematosus (LE)

LE is a group of autoimmune disorders characterized by autoantibodies to various cellular constituents, including extractable nuclear antigens and cytoplasmic membrane components. Two major forms are described: discoid LE (DLE) and systemic LE (SLE), which may involve a range of organ systems. DLE is a mild chronic form, which involves skin and mucous membranes, sometimes including the gingiva as well as other parts of the oral mucosa. The typical lesion presents as a central atrophic area with small white dots surrounded by irradiating fine white striae (Table 2). Eight percent of patients with DLE develop SLE, and ulcerations may be a sign of SLE. The characteristic dark red “butterfly” skin lesions are photosensitive, scaly, erythematous macules located on the bridge of the nose and the cheeks. The systemic type may also include skin lesions located on the face, but they tend to spread over the entire body.

3.3 | Granulomatous inflammatory conditions (orofacial granulomatosis)

Persistent enlargement of the soft tissues in the oral cavity as well as the facial region can occur concomitant with various systemic conditions like tuberculosis, Crohn’s disease (CD), and sarcoidosis. These changes are also seen as a typical symptom of the Melkerson-Rosenthal syndrome (MRS). In 1985, Wiesenfeld introduced the term orofacial granulomatosis (OFG) to describe granulomas in the absence of any recognized systemic condition (Table 2). The clinical symptoms of OFG are so similar to CD that OFG may be related to or may be CD. There is still no consensus whether OFG is a distinct clinical disorder, or an initial presentation of CD or sarcoidosis, or indeed an allergic reaction.

4 | REACTIVE PROCESSES

4.1 | Epulides

Epulis is a term often applied to exophytic processes originating from the gingiva. The term is non-specific and histopathology is the basis of a more specific diagnosis. Several of these
processes are reactive lesions, i.e., non-neoplastic proliferations with very similar clinical appearance to benign neoplastic proliferations. Usually there are no symptoms, although the reactive processes are thought to represent an exaggerated tissue response to limited local irritation or trauma, and they are classified according to their histology. True epulides include:

- Fibrous epulis
- Calcifying fibroblastic granuloma
- Pyogenic granuloma (vascular epulis)
- Peripheral giant cell granuloma (or central)

Among 2,068 cases of reactive lesions of the oral cavity, the attached gingiva with 1,331 (64.36%) cases was the most frequently affected location.

Fibrous epulis
Fibrous epulides (focal fibrous hyperplasia, irritation fibroma) are common exophytic smooth-surfaced pink masses of fibrous consistency attached to the gingiva. The size varies from small to large tumorlike processes with a diameter of several cm.

Calcifying fibroblastic granuloma
Calcifying fibroblastic granuloma (ossifying fibroid epulis, peripheral ossifying fibroma) occurs exclusively on the gingiva. The lesion, although usually smaller than 1.5 cm in diameter, can reach a larger size and rarely cause separation of the adjacent teeth and resorption of the alveolar crest.

Pyogenic granuloma
The pyogenic granuloma (telangiectatic granuloma, pregnancy tumor, vascular epulis) is rather common and shows a striking predilection for the gingiva, which accounts for 75% of all cases. When occurring during pregnancy, the influence of female sex hormones may result in a biologic behavior distinct from other pyogenic granulomas.

Peripheral giant cell granuloma (or central)
Peripheral giant cell granuloma (giant cell epulis, peripheral giant cell reparative granuloma) usually develops from the marginal gingiva. Among 2,068 cases of reactive lesions of the oral cavity, peripheral giant cell granuloma was the most prevalent lesion (30.12%). The swelling may be sessile or pedunculated, sometimes ulcerated, and the appearance may resemble pyogenic granulomas.

5 | NEOPLASMS

5.1 | Premalignant

Leukoplakia
The term “leukoplakia” refers to a white lesion of the oral mucosa that cannot be characterized as any other definable lesion. It is a clinical diagnosis arrived at by exclusion in that all other potential causes of a white lesion have been ruled out or addressed. Lesions are generally asymptomatic and cannot be rubbed off. Approximately 20% of leukoplakic lesions demonstrate some degree of dysplasia or carcinoma upon biopsy and most oral cancers are preceded by a long-standing area of leukoplakia. As a result, leukoplakia can be considered a premalignant condition. The prevalence of malignant transformation in leukoplakia ranges from 0.13% to 34%. Lesions occur most frequently on the buccal mucosa, mandibular gingiva, tongue, and floor of the mouth.

Leukoplakia manifests clinically as homogeneous and non-homogenous subtypes. The size of the lesions and clinical features are determinants of the prognosis. Thus, larger lesions and non-homogenous types of lesions imply a greater risk of malignant transformation than homogenous leukoplakia.

Verrucous leukoplakia is characterized by white papillary lesions that are covered with a thick keratinized surface. Lesions exhibiting exophytic growth and invasion of the surrounding tissues are referred to as proliferative verrucous leukoplakia, a high-risk subtype of non-homogenous leukoplakia.

Erythroplakia
Erythroplakia is the red counterpart of leukoplakia in the sense that it is a red lesion, which cannot be diagnosed as any other disease. Erythroplakia usually has a higher premalignant potential. The lesions are uncommon and seldom affect the gingiva.

5.2 | Malignant

Squamous cell carcinoma
Squamous cell carcinoma of the gingiva represents about 20% of intraoral carcinomas and occurs most frequently in the mandibular premolar and molar regions. Lesions commonly occur in edentulous areas, but they may also occur at sites in which teeth are present. Mobility of adjacent teeth is common, and invasion of the underlying alveolar bone is apparent in approximately 50% of cases. Gingival squamous cell carcinoma may mimic other oral lesions affecting the periodontium, most of which are reactive or inflammatory in nature.
Leukemia

Leukemias can be classified as acute- or chronic-based on their clinical behavior, and lymphocytic/lymphoblastic or myeloid depending on their histogenetic origin. Oral lesions occur in both acute and chronic leukemia but are more common in the acute form. The signs and symptoms are varied (Table 2). Bacterial, viral, and fungal infections including candidosis, and herpes simplex infection may also be present.82–84

Lymphoma

Lymphoma is a general term given to tumors of the lymphoid system and represents the most common hematologic malignancy. Lymphoma may originate from B-lymphocyte and T-lymphocyte cell lines. There are two main types of lymphoma: Hodgkin lymphoma and non-Hodgkin lymphoma, the former being one-sixth as common as non-Hodgkin lymphoma. In contrast to non-Hodgkin lymphoma (Table 2), oral manifestations of Hodgkin lymphoma are extremely rare.85–87

6 | ENDOCRINE, NUTRITIONAL, AND METABOLIC DISEASES

6.1 | Vitamin deficiencies

Vitamin C deficiency (scurvy)

Ascorbic acid (vitamin C) is necessary for various metabolic processes in the connective tissue as well as in the formation of catecholamines. Clinically, scurvy is characterized by gingival bleeding and soreness (Table 2), as well as by a depressed immune response. In gingival health, the concentration of ascorbic acid in gingival crevicular fluid is higher than in plasma.88

7 | TRAUMATIC LESIONS

Traumatic lesions of the gingiva may be due to a wide range of causes.89 Such lesions may be self-inflicted, iatrogenic, or accidental. Lesions, whether physical, chemical, or thermal in nature, are probably among the most common in the mouth, yet the periodontal literature contains few references on the topic.89–91

7.1 | Physical/mechanical insults

Frictional keratosis

Inappropriate toothbrushing can be injurious to the gingival tissues. Some patients believe they should actively brush the gingiva. Limited physical trauma from brushing may result in gingival hyperkeratosis, a white leukoplakia-like lesion referred to as frictional keratosis (Table 2).92

Toothbrushing-induced gingival ulceration

In cases of more violent trauma, toothbrushing damage varies from superficial gingival laceration to major loss of tissue resulting in gingival recession (Table 2).93,94 Characteristic findings in these patients are extremely good oral hygiene, cervical tooth abrasion, and unaffected tips of the interdental papillae in the site of injury. The condition has been termed traumatic ulcereative gingival lesions.93 Inappropriate dental flossing may also cause gingival ulceration and inflammation primarily affecting the tip of the interdental papillae. The prevalence of such findings is unknown.95 Diagnosis of the lesion is based on clinical findings, and an important differential diagnosis includes NG.96

Factitious injury (self-harm)

Self-inflicted injury to the gingival tissue is usually seen in young patients, and the lesions may present unusual tissue damage in areas that can easily be reached by fingers and instruments (Table 2).91

7.2 | Chemical (toxic) insults

Etching

Toxic chemical products may result in mucosal surface erosions, including reactions of the gingiva. Surface sloughing or ulceration may be related to the use of chlorhexidine,97,98 acetylsalicylic acid,99,100 cocaine,101 hydrogen peroxide,102,103 or to dentifrice detergents.104 These lesions are reversible and resolve after removing the toxic influence. Injury to the gingival tissue may also be caused by dentists’ incorrect use of substances used for endodontic purposes that may be toxic to the gingiva, including paraformaldehyde or calcium hydroxide, which may give rise to inflammation, ulceration, and necrosis of the gingival tissue if the cavity sealing is insufficient.105,106 In most instances, the diagnosis is obvious from the combination of clinical findings and patient history (Table 2).

7.3 | Thermal insults

Thermal burns of the gingiva may be prevalent due to a hurried lifestyle with intake of microwave-heated foods and drive-through coffee shops.89 Any part of the oral mucosa can be involved, including the gingiva.107 The lesion is erythematous with sloughing of a coagulated surface. Vesicles may also occur,108 and sometimes the lesions present as ulceration, petechia, or erosions, which may be painful. The clinical characteristics and the history are important for the
correct diagnosis (Table 2). Gingival injury due to cold has been described but appears to be very uncommon.109

8 | GINGIVAL PIGMENTATION

Gingival pigmentation/melanoplakia

Oral pigmentation (Table 2) is associated with a variety of exogenous and endogenous factors including drugs, heavy metals, genetics, endocrine disturbances (Addison's disease), syndromes (Albright syndrome, Peutz-Jegher syndrome), and postinflammatory reactions.110 Physiologic pigmentation is usually symmetric, occurring on the gingiva, buccal mucosa, hard palate, lips, and tongue.

Smoker's melanosis

A primary etiologic factor in melanocytic pigmentation of the oral mucosa is cigarette smoking. Smoker's melanosis occurs most frequently on the mandibular anterior facial gingiva.111,112 Melanosis gradually improves or may completely resolve upon cessation of smoking.

Drug-induced pigmentation (DIP)

DIP may be caused by the accumulation of melanin, deposits of drug or drug metabolites, synthesis of pigments under the influence of a drug, or deposition of iron following damage to the vessels.

Quinone derivatives such as quinolone, hydroxyquinolone, and amodiaquine are antimalarial drugs that cause bluish grey or black mucosal pigmentation occurring most frequently on the hard palate including the palatal gingiva.113,114

Long-term use of minocycline is associated with pigmentation of the alveolar bone and teeth. When changes in bone are viewed through relatively thin overlying mucosa, the gingiva may appear grey and is seen primarily in the maxillary anterior region. True minocycline-induced soft tissue pigmentation is much less common and occurs primarily on the tongue, lip, buccal mucosa, and gingiva.115,116

Amalgam tattoo

Pigmentation of the oral mucosa due to amalgam is frequently seen in the gingiva and alveolar mucosa. The lesion is a well-defined bluish, blackish, or greyish discoloration, which is not elevated (Table 2).117,118 Radiographic imaging may demonstrate underlying amalgam debris.

ACKNOWLEDGMENTS AND DISCLOSURES

The authors report no conflicts of interest related to this review paper.
